Short Answer Test

1. Suppose a software system is developed for a **Smart Banking System** where customers can open accounts, transfer funds, and pay utility bills.

(a) Explain the following object-oriented concepts:

- Class
- Object
- Message Passing
- Encapsulation
- Polymorphism

(b) Describe the following object relationships:

- Association
- Aggregation
- Composition

(c) Explain how these concepts improve software reusability and maintainability in a banking system.

(5 Marks)

Answer:

(a) Explain the following object-oriented concepts

1. Class

A **Class** is a blueprint or template that defines the properties (attributes) and behaviors (methods) of objects.

Example (Smart Banking System):

- **Class:** Customer
- **Attributes:** customerID, name, address, phoneNumber
- **Methods:** openAccount(), transferFunds(), payBill()

2. Object

An **Object** is an instance of a class that contains actual data and can perform the actions defined in the class.

Example:

- **Object:** Customer1
- **Name:** Sayed Fazal

- **Account Number:** 10024567
- **Balance:** \$5,000

This object can transfer funds and pay bills.

3. Message Passing

Message Passing is the communication between objects through method calls. One object requests another object to perform a task.

Example:

When a customer transfers money:

- Customer object sends a request to the Account object.
- The Account object checks the balance and transfers the amount.
- The Transaction object records the transaction.

4. Encapsulation

Encapsulation is the process of hiding data and allowing access only through public methods, ensuring data security.

Example:

The account balance is declared as a private variable.

Private:

balance

Public Methods:

deposit()

withdraw()

getBalance()

5. Polymorphism

Polymorphism allows the same method to perform different tasks depending on the object calling it.

Example:

Method:

calculateInterest()

Different account types calculate interest differently:

- Savings Account → 5% interest

- Current Account → 0% interest
- Fixed Deposit → 7% interest

The same method behaves differently for each account type.

(b) Describe the following object relationships

1. Association

Association is a relationship where two independent objects communicate with each other.

Example:

- Customer ↔ Bank Account

A customer owns one or more bank accounts, but both can exist independently.

Customer ----- BankAccount

2. Aggregation

Aggregation is a "has-a" relationship where one object contains another object, but the contained object can exist independently.

Example:

- Bank → Employees

Employees continue to exist even if a particular bank branch is closed.

Bank ◇----- Employee

(◇ = Hollow Diamond)

3. Composition

Composition is a strong "part-of" relationship where the contained object cannot exist without its parent object.

Example:

- Bank Account → Transaction History

If the bank account is deleted, its transaction history is also deleted.

BankAccount ◆----- Transaction

(◆ = Filled Diamond)

(c) How these concepts improve software reusability and maintainability

OOP Concept	Benefit in Smart Banking System
Class	Reusable blueprint for creating multiple customers, accounts, and transactions.
Object	Represents real-world banking entities, making the system easier to understand.
Message Passing	Enables communication between different modules without tight coupling.
Encapsulation	Protects sensitive banking information such as account balance and PIN from unauthorized access.
Polymorphism	Allows the same operation (e.g., calculateInterest()) to work differently for different account types, reducing duplicate code.
Association	Models relationships like Customer–Account without making objects dependent on each other's lifecycle.
Aggregation	Allows independent objects such as employees or customers to be reused in different parts of the system.
Composition	Maintains data integrity by ensuring dependent objects (e.g., transaction history) exist only with their parent account.

2.Consider developing a **Smart Healthcare Management System**.

(a) Explain the following object-oriented design principles:

- Abstraction
- Encapsulation
- Modularity

(b) Describe the following SOLID principles:

- Liskov Substitution Principle (LSP)
- Interface Segregation Principle (ISP)

(c) Explain how these principles improve software quality and flexibility.

(5 Marks)

Answer:

(a) Object-Oriented Design Principles

1. Abstraction

- Hides implementation details and shows only essential features.
- **Example:** Doctors access patient records without knowing database operations.

2. Encapsulation

- Protects data by restricting direct access through methods.
- **Example:** Patient records are accessed using get() and set() methods.

3. Modularity

- Divides the system into independent modules.
- **Example:** Patient, Appointment, Billing, and Pharmacy modules.

(b) SOLID Principles

1. Liskov Substitution Principle (LSP)

- A subclass should be replaceable for its parent class without affecting program behavior.
- **Example:** Cardiologist can replace Doctor.

2. Interface Segregation Principle (ISP)

- Classes should implement only the interfaces they need.
- **Example:** Billing and Appointment interfaces are separate.

(c) How these principles improve software quality and flexibility

Principle	Improvement in Smart Healthcare Management System
Abstraction	Hides complex implementation details, making the system easier for doctors, nurses, and administrators to use.
Encapsulation	Protects sensitive patient records by restricting direct access and allowing controlled updates.
Modularity	Separates the system into independent modules, making development, testing, and maintenance easier.
Liskov Substitution Principle (LSP)	Allows specialized healthcare professionals (e.g., Cardiologist, Dermatologist) to replace a general doctor object without changing program behavior.
Interface Segregation Principle (ISP)	Ensures each user or component implements only the required functions, reducing unnecessary dependencies and improving maintainability.
